

Ideation Phase

Brainstorm & Idea Prioritization Template

Date	03 October 2026
Team ID	SWTID-2026-5622
Project Name	Script-Controlled ACL – Restrict Access Based on Field Value
Maximum Marks	4 Marks

Step-1: Team Gathering, Collaboration and Select the Problem Statement

Brainstorming provides a free and open environment that encourages everyone within a team to participate in the creative thinking process that leads to problem solving. Prioritizing volume over value, out-of-the-box ideas are welcome and built upon, and all participants are encouraged to collaborate, helping each other develop a rich amount of creative solutions.

For this project, the brainstorming focuses on improving ServiceNow record-level security through a Script-Controlled Access Control List (ACL) that evaluates field values before allowing a user to access a record.

Problem Statement

How can a ServiceNow application restrict access to individual records dynamically based on a record's field value, while still supporting role-based permissions and maintaining security, scalability, and maintainability?

Step-2: Brainstorm, Idea Listing and Grouping

1. Create a scripted ACL that checks a selected field value before granting access.
2. Combine role-based access with field-value conditions.
3. Use a Script Include to centralize reusable access-validation logic.
4. Support ownership-based access so record owners can access permitted records.
5. Add state-based restrictions, such as limiting access to records in specific business states.
6. Apply different access rules for different user groups or roles.
7. Log denied access attempts for security auditing.
8. Keep the ACL logic efficient to reduce performance impact on record queries.
9. Design the solution so field names, roles, and policy values can be maintained without duplicating logic.
10. Extend the model later for hierarchical or contextual access rules.

Step-3: Idea Prioritization

Rank	Brainstormed Idea	Security Impact	Feasibility
1	Script-controlled ACL based on field value – Validate a record's field value before granting access.	High	High
2	Role + field-value validation – Combine user roles/groups with field-based conditions to prevent unauthorized access.	High	High
3	Ownership + business-state validation – Consider record ownership and the current business state when deciding access.	High	Medium
4	Reusable Script Include – Centralize access-validation logic for consistent security checks.	High	Medium
5	Access-denial auditing – Track denied-access events for security monitoring and troubleshooting.	Medium	High
6	Performance optimization – Keep ACL scripts efficient and avoid unnecessary database operations.	Medium	Medium

Final Prioritized Solution

The team's brainstorming therefore leads to one cohesive solution:

**Field-Value ACL → Role/Group Validation → Ownership & State Validation → Reusable Script Include
→ Auditing → Performance Optimization**

That makes the project progression much stronger because it shows:

Basic Access Control → Context-Aware Security → Reusable Architecture → Monitoring → Scalability
